THIRD MELBOURNE GENERAL CATALOGUE.

INTRODUCTION.

The Second Melbourne General Catalogue of 1,211 Stars for the Equinox of 1880 was published in 1889, and comprised the results of observations made with the "old" transit circle of 5 inches aperture in the years 1871·0–1884·7. In 1884 a new transit circle, by Troughton and Simms, of larger dimensions and power, was installed, and all the observations upon which is based the Third Melbourne General Catalogue, now presented, were made with the new instrument during the period 1884·7–1894·0.

The MS. of this catalogue was prepared fifteen years ago. The reason for its long delayed publication is that, since 1889, and until recently, the Government of Victoria found it inexpedient to authorize the printing of any astronomical work of the Melbourne Observatory.

It was intended, in accordance with previous practice, to publish at the proper time, the annual catalogues of the stars observed in the years 1884–1894, the MSS. of which had been regularly prepared for the purpose, in continuation of the series of volumes entitled *Melbourne Results of Astronomical Observations*, which contain, among other records, all our Annual Star Catalogues to the end of 1883; but, for the reason stated above, no further volumes were added to this series after the issue, in 1889, of Volume VII., and, under the circumstances, it seemed desirable to give precedence to the publication of the Third General Catalogue.

This catalogue contains the mean positions of 3,068 stars for the equinox 1890, in which total number are included :—

(1) Fundamental stars used for the determination of clock-error and azimuth;
(2) Guide-stars for the astrophotographic zones (−11° to −14°) and (−65° to −90°);
(3) Stars used in connexion with observations of comets;
(4) Some stars of the "Connaissance des Temps" and "Berliner Jahrbuch" observed at the request of the Bureau des Longitudes and of the late Prof. Auwers;
(5) Various lists of stars observed for the late Sir David Gill in connexion with his heliometer investigations at the Cape Observatory.

The general routine which was followed throughout in making and reducing the observations, and in computing, from the separate results, the mean places for the annual catalogues of the period 1884·7–1894·0, was practically similar to that which has been fully described in Vols. V., VI., and VII. of the "Melbourne Results of Astronomical Observations." The processes employed in combining the separate star places in the *Annual Catalogues* to form the concluded mean places referred to the Equinox of 1890, as given in the present catalogue, are identical with those described in the Second Melbourne General Catalogue for the Equinox of 1880, to all of which publications reference can be made.

An account of the instrument with which the observations were made will be found in the Report of the Government Astronomer attached to the *Nineteenth Report of the Board of Visitors to the Melbourne Observatory* (1884), from which the following abstract has been taken :—

> "The instrument is a fine specimen of Troughton and Simms' well known skill in the construction of astronomical instruments of this class, and is very similar in form and dimensions to those constructed by the same firm for the Cambridge Observatory in England, as well as for the Cambridge Observatory of Boston, United States of America. The telescope has an aperture of 8 inches, and focal length of 108 inches; axis, 52 inches long, with steel pivots of 4½ inches diameter. The pivot-bearings are carried on two short iron pillars, resting on massive stone piers, which rise about 5 feet above the floor. The axis carries two divided circles, one on each side of the telescope, of which one is fixed, the other movable about the axis. The circles—3 feet in diameter—are read by a reading telescope and four microscopes carried on gun-metal circles, attached to the short iron pillars already mentioned. . . . .
>
> The form of axis of this instrument differs considerably from others of this class, and is an innovation designed to obviate the troublesome flexure of the axis, to which large transit instruments are often subject. Instead of the casting forming the axis being in the form of two cones with a central cube as usual, it takes the form of two cones united by a cylinder, crossed by another cylinder for carrying the eye and object ends of the telescope. . . . . The collimators, which rest on piers at the north and south end of the Transit Room, have objectives of 6 inches in diameter, and are reciprocally visible through a perforation of the same aperture in the central part of the axis of the transit instrument.

670953

The arrangements for the illumination of the circles and telescope are well designed and very effective, one source of light opposite either end of the axis giving illumination to the four microscopes and reader of the circle, as well as bright or dark field illumination for the telescope micrometer wires."

Throughout the observations the instrument has been used in the position fixed circle W., and the readings of the fixed circle taken with its four microscopes.

The adopted position of the instrument is—

λ 9h. 39m. 54s. 20 E.

ϕ 37° 49′ 53·35″ S.

The *personnel* who, under the supervision of the Director, the late R. L. J. Ellery, took part in the observations and carried out the computations, so far as the preparation of the annual catalogues for the years 1884–1894 required, comprised the late Mr. E. J. White, Chief Assistant of the Observatory, in charge of the Meridian Department till 30th September, 1892, on which date he retired, having reached the age limit prescribed by the Public Service Act, and the following :—

Mr. J. E. Gilbert, from the beginning of the period till May, 1887 ;

Mr. G. A. M. Pringle, from the beginning of the period till March, 1890 ;

Mr. W. J. Swan, from September, 1887, to the end of the period ;

Mr. F. N. Ingamells, from January, 1888, to August, 1892 ;

Mr. E. T. Quayle, from May, 1890, to the end of the period.

After 30th September, 1892, the Meridian Department was placed in my charge, and the actual preparation of this catalogue was commenced and completed under my direct supervision, after the retirement of the Government Astronomer, R. L. J. Ellery, which took place on 30th June, 1895, most of the computations having been made by the Rev. E. J. White, jun.

In later years, the whole of the work was gradually revised, and several extracts and a copy of the full MS. were supplied, at their request, to the late Prof. Auwers and to the late Prof. Boss, at various times between 1902 and 1915. The work of revision was conducted by Mr. C. J. Merfield and other Observatory assistants.

The plan adopted in the earlier catalogues of this Observatory in regard to the extent and distribution of the data for each catalogued star has not been entirely followed. The third term of the precession, in both coordinates, has been omitted, and the secular variation of the annual precession has been substituted for the " second term of the precession P' or p' " as previously adopted. Other omissions were made to enable all the essential data to be tabulated, for each star, in fifteen columns, occupying a single page, instead of 32 columns, which required two pages in the older form. These omissions are—the number of observations of the star's magnitude, Bessel's star numbers, and the reference numbers to the stars in earlier catalogues of southern stars.

The following additional remarks will further explain the formation and arrangement of the data tabulated under the various columns of the catalogue with the exception of the first, sixth, and twelfth columns, which require no elucidation.

In the second column the star magnitudes which are printed in ordinary type depend on the estimations noted by the transit observers, being the mean of all the magnitude observations made. The heavier type or an asterisk represents magnitudes adopted from other authorities as shown in the list given. The magnitudes of fundamental stars were taken from Newcomb's *Catalogue of Fundamental Stars for* 1875–1900, or from the *Revised Harvard Photometry.* These are printed in larger heavy type.

The system employed in the nomenclature of stars and the notation, as shown in the third column, the method of computing the mean year of observation in the fifth and eleventh column, and the authorities and rules followed in deriving the proper motions, noted in the ninth and fifteenth columns, are completely in accord with the description of these particular items given in the introduction of the Second Melbourne General Catalogue for 1880·0, from which all desired information in these respects may be gathered.

In the third column, M.Z. indicates that the star was one selected, to serve as guide star for the astrographic catalogue, from an MS. catalogue of zone observations made at the Melbourne Observatory, and D.M. refers to the Bonner Durchmusterung, 1855. In the footnotes, Wa. Z. refers to Gilliss's zone observations, made at Santiago de Chile.

In regard to the concluded Mean Right Ascensions for 1890·0, in the fourth column, it is proper to point out that the right ascensions of the clock stars are involved in the determination of the clock errors, for which purpose the right ascensions of these stars, given by the Nautical Almanac (with the corrections provided by the Royal Observatory of Greenwich applied), were used, and that the catalogued right ascensions of such stars are not, therefore, independent. This limitation affects also the right ascensions of stars which have been employed for the determination of the azimuth error.

Sets of at least six clock stars and four circumpolar stars, two at upper and two at lower meridian passage, were usually observed in each night's programme.

ADOPTED POSITIONS OF AZIMUTH STARS.

The right ascensions of stars whose proper motion is given have been reduced to the epoch 1890·0 (equinox 1890·0) by the application of the proper motion; where the proper motion is not given the Right Ascension refers to the mean year of observation and to the equinox 1890·0.

The annual precessions in R.A., shown in the seventh column, were computed from the formula :—

$$P = 3^{s}\cdot07253 + [0\cdot12609] \sin \alpha \cot \Delta,$$

where P is the annual precession in R.A., α the mean Right Ascension, and Δ the mean North Polar Distance for 1890·0. The co-efficients are those of Prof. Peters.

The secular variations in the eighth column were prepared by the aid of "Tables pour le Calcul des Reductinso Stellaires," par F. Folie, using the tabulated quantities without correction, as their variation from the epoch 1870 to 1890 was considered negligible.

The proper motions, given in the ninth column, were used to reduce the observed position from the mean date of observation to the epoch 1890·0, which remark applies also to the proper motions in North Polar Distance, in column 15.

The tenth column contains the Mean North Polar Distances for 1890·0. In the formation of these values, Bessel's "Refraction Tables," given in the "Appendix to Greenwich Observations, 1853," were used.

In column 13, the given precessions in N.P.D. were computed from the formula—

$$p' = -[1\cdot30218] \cos \alpha.$$

The secular variations of the annual precession in N.P.D. contained in the fourteenth column, were obtained by means of Folie's tables, in the manner described in connexion with the secular variation of the annual precession in Right Ascension.

No corrections have been applied for the division errors of the circle. The errors of the degree divisions were investigated in 1911 (Circle E) and the results of the investigation are given below. A fuller account will be published in the Introduction to the General Catalogue for 1900.

OBSERVED CORRECTIONS FOR DIVISION ERROR.

CORRECTIONS TO THE MEAN OF THE FOUR MICROSCOPES.
